

## OpenROAD 6.2 – New Features in Detail, Part I

New in OpenROAD 6.2 – For OpenROAD developers.  
Third of four presentations. Assumes attendance at the first.

## Overview

### ➔ OpenROAD 6.2 – New generic features in more detail, Part I

- The third of four presentations covering OpenROAD 6.2
  - ➔ This presentation is the first of two reviewing in detail the new features in this release
- Features illustrated in the presentation will require the first OpenROAD 6.2 patch
  - p14746 or later

This presentation assumes that you have seen the Overview presentation.

If you have not, we recommend that you first view the recording of the Overview presentation, available at

<https://actian.webex.com/actian/j.php?MTID=m013e2f1d62551cb8f21d7f92dd145f6f>

p14746 OR 6.2.0 (int.w32/00)

## OpenROAD 6.2 Objectives

- OpenROAD 6.2 is the outcome of a set of objectives pursued systematically over the last few years:
  - I - Provide specific support for certain in-demand business requirements
  - II - Reduce the cost of OpenROAD development (time, headcount, skill, maintenance)
  - III - Improve the deployment of OpenROAD
  - IV - Provide generic enabling facilities to underpin the new features and also future ones
  - V - Implement all these changes in a way that logically extends the OpenROAD metamodel and fills important gaps in it
- The fourth objective is addressed in this and the subsequent presentation

## In the Overview Presentation (reminder):

### → Meeting Business Requirements

- Restyling to up-to-date look-and-feel(s)
- Same-code (unchanged code) transformations
- Generated userclasses and displays
- Active-map and Booking/Allocation capabilities
- Richer out-of-the-box capabilities
- Easier deployment

### → Improving OpenROAD ROI

## Meeting OpenROAD 6.2 Objectives ...

- IV - Providing generic enabling facilities to underpin the new client-oriented features, and future ones

#### IV - Providing generic enabling facilities to underpin the business-need features, both current and future

1. Bitmapped backgrounds with built-in bordering and double-buffering
2. Compound bitmaps, sprites and animations
3. Tagged Values/Items
4. Storable defined-behaviours
5. Helper classes and Setup frames
6. Many enabling property and method changes to field and data classes
  - TreeViews, TableFields, TabFolders; String & BitmapObjects; and much more
7. Enhanced PropertyChanged facilities
8. Database and display heuristics
9. Downloadable IngresNet
10. LoadnRun deployment

Items 6 to 8 are covered in the fourth presentation

Items 9 and 10 were covered in the second presentation

❑ Bitmapped backgrounds with built-in bordering and double-buffering ①

→ Field appearance in commercial applications has become immensely complicated and flexible

■ Static rectangular backgrounds are the exception not the rule

■ The comprehensive property-based model is too unwieldy and obscure, and draws too slowly if unbuffered

→ Paradigm change

■ Treat field appearance as a single background image, switchable

■ Incorporate bordering, autosizing, transparency, opacity, gradients

- Implemented as BitmapObject methods

■ Double-buffer the drawing of the field appearance

■ Reimplement to optimize the new approach

→ Still retain property-based model for backward compatibility

8

Confidential © 2014 Actian Corporation

Numbers in circles in the title refer to the numbering of the sub-objectives on the previous page

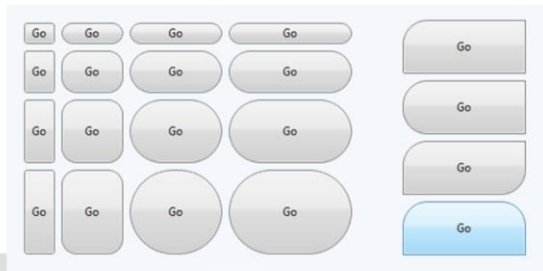

## ... Bitmapped backgrounds with built-in bordering and double-buffering ...

### → Applied using either Property Inspector, or 4GL code:

- BgDisplayPolicy attribute: BDP\_BORDERED and BDP\_CORNERED
- BgPattern attribute: FP\_BITMAPCLEAR
- BgBitmap attribute: CornerSize setting

### → Effects:

- The background interior resizes with the field, but borders and corner are preserved
- The cornering can be in the bitmap, or applied to the bitmap
- All the following are copies of the same field with the same BgBitmap:

9 Confidential © 2014 Action Corporation

## Demo:

### D201504\_BitmappedBkgFields -cBitmappedBkg\_Rounding

Note that all these fields are identical apart from size: same bitmap, same BgDisplayPolicy (BDP\_CORNERED), BgPattern (FP\_BITMAPCLEAR), CornerSize (3 pixels).

Note that the appearance of the field, other than the text, is entirely due to the bitmap, including the edges and corners.

Click the Go button (to apply a variety of cornersizes to the fields)

Note that the borders are still preserved, the corners are transparent and antialiased at all radii, the corners can be individually rounded.

```
/*
**      Set a rounding of 5 pixels for each corner
*/
btn.UpdBackground(cornersize=5);

/*
**      Set independent roundings for each corner
**      (this one curves the top two corners, rightangles the bottom two)
*/
#define $TL      '256**0'      -- topleft
#define $TR      '256**1'      -- topright
#define $BR      '256**2'      -- bottomright
#define $BL      '256**3'      -- bottomleft
```

```
btn.UpdBackground(cornersize=25*$TL + 25*$TR + 0*$BR + 0*$BL);
```

Can also define `BorderWidth`, `BorderStyle`.

❑ Compound Bitmaps: Switching borders, rounding, gradients, highlights ① ②

➔ BitmapObjects can contain up to 255 subimages (and 255 sprite "icons")

- Highlighting is just switching the subimage index
  - Using UpdBackground() with ImageIndex parameter
- Windows7 requires 10 different subimages:

One ButtonField → Go

One BgBitmap, with ten subimages

normal  
highlight  
dimmed  
focus pulse  
focus  
default pulse  
default  
focus highlight  
focus down  
focus drag

10 Confidential © 2014 Action Corporation

## Demo:

D201504\_BitmappedBkgFields -cBitmappedBkg\_ImageSwitch

Click the Go button

Note that on the left is the single bitmap (containing 10 images) that all the buttons on the right use.

Note that initially the imageindex is unset, so all of the fields are using the first image

Click the Go button

Note that each field now has a different imageindex between 1 and 10; that is the only thing that has changed.

```
/*
**      Display the buttonstyles
*/
for i = 1 to styler.ChildFields.LastRow do
    btn = styler.ChildFields[i];
    /*
    **      Change the imageindex
    */
    btn.UpdBackground(imageindex=i);
endfor;
```

Borders can be range of styles (plain, concentric, 3-D, adhoc, none); plain borders can be any width; concentric borders can have up to 3 layers.

Key properties are: UpdBackground method; BgBitmap, BgDisplayPolicy and BgPattern attributes.

## Compound bitmaps, sprites, animations, defined behaviors ②

→ Apply sprite icons (and sectors) to ActiveFields using:

- UpdBackground method: Spritemap and Sctormap parameters, or
- InputEvent LoadEventBehavior/TriggerEventBehavior methods

Each dot or line on the graph is a sprite

Each BgBitmap has three sprite icons

To run this frame takes just 100 executing statements at runtime ...

11 Confidential © 2014 Action Corporation

### Demo:

D201504\_DefinedResponses\_Sprites -cProgressBars\_coded

Click the first button; when second button activates, click it

```

/*
** List and count and graph the imagefiles in each of the listed folders
*/
for i = i + 1 to folders.LastRow do
    foldername = folders[i].Value;
    /*
    ** Execute a Windows command to list the image files; read in and parse the list file;
    ** Add the count of found bitmaps to the total bitmaps of this type;
    */
    call system :cmd; //creates list in file <fname> of bitmaps in the folder <foldername>
    filestring.FileHandle = fname;
    fromct = ct;
    ct = ct + filestring.Split(delimiter=HC_NEWLINE).LastRow;
    /*
    ** Define a sprite as a line between the old value and the new; display the sprite;
    ** Tell the progress bar how far (%) we have got
    */
    height = (ct-fromct)/scale + 1;
    SDS[j].SetAttribute(spritesourceindex=j, x=i, y=graphh - fromct/scale - height,
        height=height, width=width);
    SDS[1].ApplySpriteMap(targetfield=field(graph), descriptors=SDS, operation='add');

    step = (i*100)/folders.LastRow;

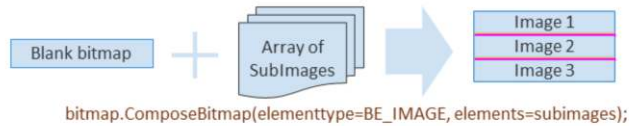

```

```
        IE.TriggerEventBehavior(location=progbars,
                                eventkey=progbarskey + '#' + varchar(step) + ',' + varchar(step));
    endfor;
```

## More about Compound Bitmaps

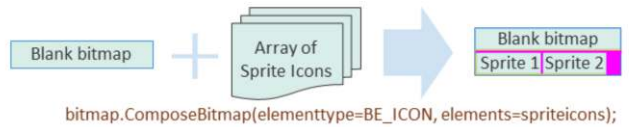

### ➔ Created using ComposeBitmap (or a bitmap editor ...)

- To create a bitmap containing sub-images:

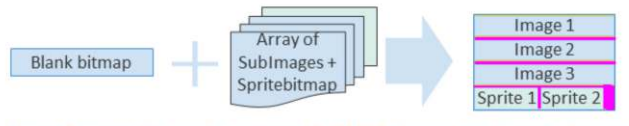

```
bitmap.ComposeBitmap(elementtype=BE_IMAGE, elements=subimages);
```

- To create a bitmap containing sprite icons:

```
bitmap.ComposeBitmap(elementtype=BE_ICON, elements=spriteicons);
```

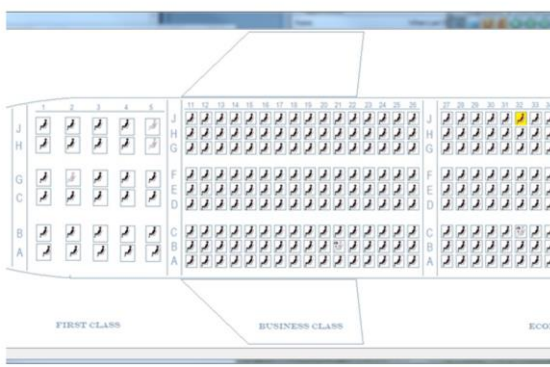

- To create a bitmap containing images and sprites:

```
bitmap.ComposeBitmap(elementtype=BE_IMAGE, elements=subimages, hasicons=TRUE);
```

## More about sprites – aircraft seating allocation example

- Seats are defined as sectors – 300 of them – stored in the bitmap in a single “sectormap” string. Each sector definition includes the seat code.
- Passengers are defined as sprites – 295 “passenger” sprites, 3 “available” sprites, 1 “maybe available” sprite, 1 “unhappy passenger” sprite, positioned by assigning them to a sector (seat), and stored within the bitmap in a single “spritemap”.
- Sprites can be dragged (and the mouse changed to indicate draggable sprites) – the rest is just logic code.

- The display shows just 1 field, with 1 simple BgBitmap, and 4 sprite images that are attached to the bitmap at runtime
- See SpriteDescriptor Helper Class (later) for more details about sprites.

13 Confidential © 2014 Action Corporation

```

...
/*
** Map the Economy Class seats (as sectors)
*/
for row = 27 to 44 do
  for aisle = 1 to 11 do
    ...
    descriptor = descriptors[indx];
    descriptor.SetAttribute( spritesourceindex=1, name=name, width = 20,
height = 22,
                        sector=1, gravity='CC', x=x, y=y);
  endfor;
endfor;

SD.ApplySectorMap(targetfield=field(airplane), descriptors=descriptors,
operation='apply');

/*
** Put passengers on the seats (as sprites)
*/
for l = 1 to passengers.LastRow do

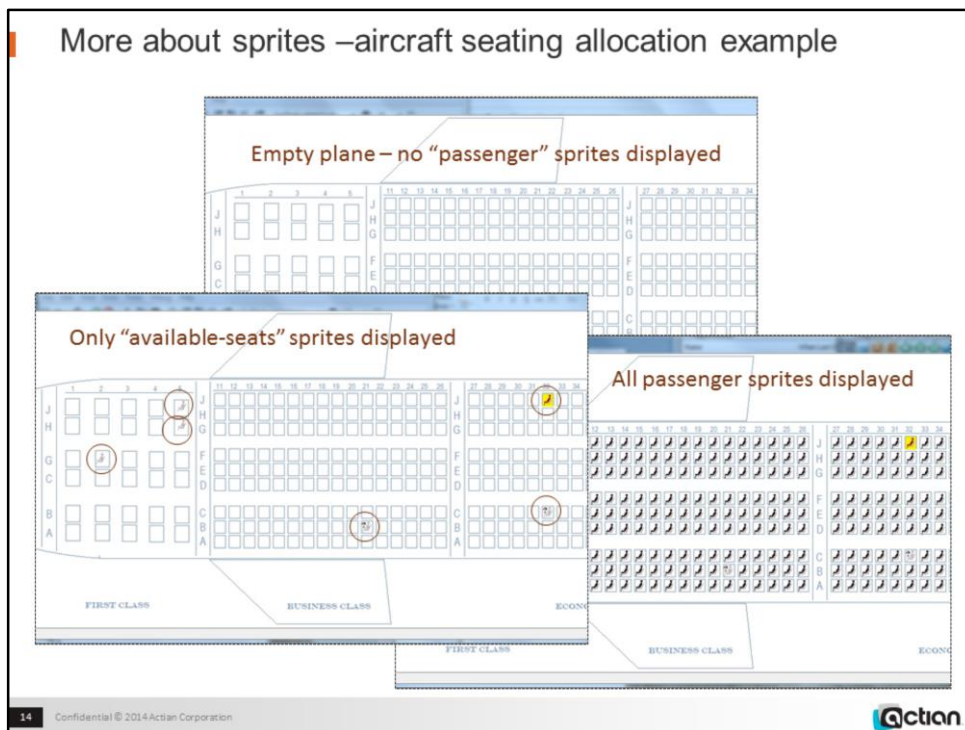

```

```

...
        descriptor = descriptors[indx];
        descriptor.SetAttribute( spritesourceindex=indx, name=seatname,
flags=responseflags,
            sector=seatsector, gravity='CC', x=0, y=0);
    endfor;
endfor;

SD.ApplySpriteMap(targetfield=field(airplane), descriptors=descriptors,
operation='apply');

```

### Demo:

w4gldev runimage workbnch.img -Tall -/appflags profile=or62demos  
application=allocationsystems component=airlineseating command=openscript#561

Note that the code is creating a `spritedescriptor` definition for each Economy seat, treating it as a sector, computing each seat’s size and x & y. Then the code creates a `sectormap` from the descriptors, and stores it in the “seating plan” bitmap.

Go to line 265

Note that whenever a passenger is dragged to a new seat, the code just calls the `LastInputAction` method, once to identify the passenger (`action='mousedown'`) and once to identify the seat (`action='mouseup'`).

## Bitmapped backgrounds: Transparency, Opacity ①

→ Apply transparency and opacity to ActiveFields (and to sprite icons)

- Using FP\_BITMAPCLEAR, UpdBackground with opacity (or spritemap parameter)
 

```
overfield.BgPattern = FP_BITMAPCLEAR;
overfield.UpdBackground(cornersize=1, opacity=0.75);
```

Transparent region of field background

Opaque (75%) region of field background

bitmapped background of underlying field

15 Confidential © 2014 Actian Corporation

### Demo:

**D201504\_BitmappedBkgFields -cBitmappedBkg\_Opacity\_Transparenc**

Run the frame

Note that the frame background displays a satellite image of the world, as a Mercator projection

Rightclick the frame

Note that the world image is overlaid with a field that has transparent areas (forming the letters of the word "OpenROAD"), and translucent areas (75% opacity).

### Demo:

**w4gldev runimage workbnch.img -Tall -/appflags profile=or62demos**

**application=d201504\_bitmappedbkgfields**

**component=bitmappedbkg\_opacity\_transparenc command=openscript**

Note that the frame background displays a satellite image of the world.

Note that there is a buttonfield overlaying the background, but that field initially is FP\_CLEAR and has no text, so you cannot see it.

Rightclick the frame

Note that the code simply makes the upper field's background transparent (FP\_BITMAPCLEAR) and translucent (opacity=0.75, set using the UpdBackground method)

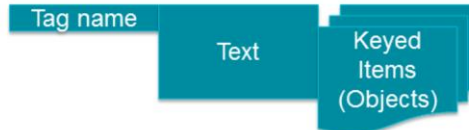

```
/*  
** Make the overlying field transparent and 75% opaque  
** (overfield is a buttonfield with an image of the word "OpenROAD".  
Underneath is the frame's  
** topform, displaying a satellite image of the world)  
*/  
overfield.BgPattern = FP_BITMAPCLEAR;  
overfield.UpdBackground(cornersize=1, opacity=0.75);
```

## ❑ Tagged Value/Items ③

→ Need to make data and objects more systematically accessible

- Tagged Values/Items

→ Tagged values are named-value objects and collections.

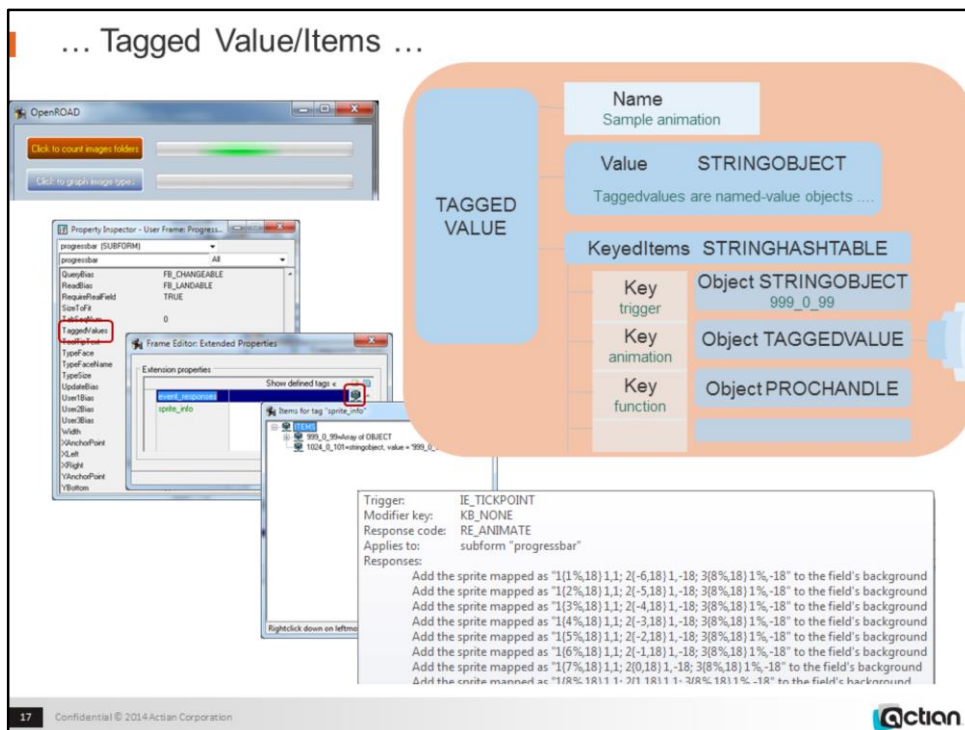

→ Every field has them, every frame, class, application, attribute.

→ They allow you to store anything you want, where you need it, always available, with immediate keyed access:

- Values, text, search-markers, lookuplists, procedures, resources, packages, objects of any type

→ When the frame or class is saved, taggedvalue contents save as well.

### Demo:

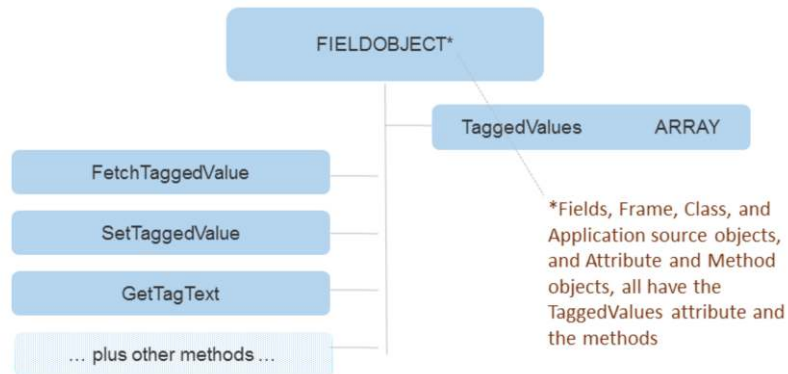

w4gldev runimage workbnch.img -Tall -/appflags profile=or62demos  
application=d201504\_definedresponses component=progressbars\_predefined  
command=open  
Continue as shown.

In this example, the tooltip text in the TaggedValue Editor Items Dialog is displaying a description of the stored defined behavior that drives the marquee bar.

- the marquee behavior is actually a sprite-based animation that moves the green pulse to and fro
- The description is derived by examining and interpreting the KeyedItems that make up the behavior definition

The behavior is actually stored in the marquee field, as a TaggedValue object called ("event\_responses"), containing a collection of Items defining the required behavior. No 4GL code or event is required for the animation.

## Using TaggedValues in the 4GL

### → Example use of Value:

- storing and retrieving the previous value of a numeric field:

```
fld.SetTaggedValue(tag='lastvalue', textvalue=Varchar(fldvalue)); //stores number
lastvalue = Int4(fld.GetTagText(tag='lastvalue')); //gets number
```

```

/*
** Store the field's value (numeric in this example);
** Retrieve the stored value;
** Retrieve the entire taggedvalue
*/
fld.SetTaggedValue(tag='lastvalue', textvalue=Varchar(fldvalue)); //stores the
number
lastvalue = Int4(fld.GetTagText(tag='lastvalue')); //gets the
number
lastvalue_tag = fld.FetchTaggedValue(tag='lastvalue'); //gets the
taggedvalue itself

```

Tagged Items

Tag name

Text

KeyedItems (Objects)

- Any number, any complexity
  - Items can themselves be arrays, hashtables, taggedvalues
- Items are hashed - key for each item
- Pre-store whatever “package” your business function needs
  - Even procedure-handles, executables, database contents, ...
  - Methods to make this easy
- Then save the component, and your package saves with it
- When the application starts up, your package is in the component, ready to go
  - Including the procedures

19

Confidential © 2014 Action Corporation

## “Procedure-handles”: ProcHandles

ProcHandles have a huge advantage over Call Procedure as a way of invoking frame or field or userclass procedures:

- Call procedure myproc (or call procedure :myprocname) only works if the calling code can see the procedure-declaration – in practice this limits callable local procedures to those declared in the same script

```
call procedure myproc(...parameters...);           //works only if procedure
declaration is visible
```

- The ProcHandle for myproc incorporates the declaration, so it works from outside the frame or userclass – under the right circumstances it can even be saved and restored, or exported and reimported, and it will still work

```
/*
** Create ProcHandle for this procedure
*/
myprochandle = myUserclass.GetProcHandle(name='myproc');

/*
** Execute procedure from different frame, method, procedure
*/
myprochandle.Call(...parameters...);           //works in much wider range of
```

circumstances

## TaggedValue Keys

### → The tag name

- Accesses the tagged value itself

### → The itemkeys

- Each item in the tagged value KeyedItems has its own key
- Keys are varchar(256)
- Access methods are FetchTaggedValue and SetTaggedValue

### → Example: storing and retrieving the current triggerfield and event

- Very useful when the user clicks a button, and you need to know which field they were last working on (might not be the inputfocusfield ...)

```
form = curframe.TopForm;  
status = form.SetTaggedValue(tag='lasttrigger#field', item=curframe.TriggerField);  
status = form.SetTaggedValue(tag='lasttrigger#event', item=curframe.CurEvent);  
form.FetchTaggedValue(tag='lasttrigger#field', item=Byref(triggerfield));
```

20

Confidential © 2014 Action Corporation

```
/*  
** Store the last triggerfield and last event in the frame's topform  
** ...  
** Get the last triggerfield (later on, when we need it)  
*/  
form = curframe.TopForm;  
status = form.SetTaggedValue(tag='lasttrigger#field', item=curframe.TriggerField);  
status = form.SetTaggedValue(tag='lasttrigger#event', item=curframe.CurEvent);  
...  
form.FetchTaggedValue(tag='lasttrigger#field', item=Byref(triggerfield));
```

## Availability and formatting

### → TaggedValues can be

- Runtime, designtime, or both
- Temporary or permanent
- Formally defined or ad-hoc

Use the Availability property for both of these

Use TagDefinitions for formal tags

- When you are preparing defined behaviors, you don't want your mistakes saved! So the "temporary" setting is very useful

```
tagged_value.Availability = TVA_TEMPORARY;
```

- But you do not need to use it directly: use the InputEvent LoadEventBehavior, which includes a MakePermanent parameter.

- The TaggedValue Editor uses formally defined tags

- to ensure that the important tags for classes, attributes and fields are listed, whether or not they have yet been set
- The Files subdirectory contains TagDefinition files to support this
- You can define your own – details are in the Language Reference Guide

## Advantages of using Tagged Values

### → Definition, not code

- Tagged values reach the areas that database data-definition and object oriented structuring can't reach
  - Previously, such content was coded in at runtime, where that was even possible
- Information exactly where it is needed – avoiding Hansel and Gretel code
- Much less, much simpler code

### → Developers can add properties they need directly, instead of raising SIRs ...

- Restore the previous value? Public name for error messaging? Allowed values for this entryfield or attribute? Corresponding database column? Input help?

### → Certain features are only possible with tagged items

- Animations, flyins, Windows 7 pulsing, etc:
  - Pre-store a list of intervals, a multi-image bitmap, a sequence list, and a trigger, all in the one taggedvalue
  - 6.2 does the rest – no code required

22

Confidential © 2014 Action Corporation

Examples of Hansel and Gretel code / Adhoc trails:

- passing an incrementing counter to a usevent as the MessageInteger
- including the datatype of a variable in the variable's name

...

Advantages of using Tagged Values ...

→

OpenROAD itself makes increasing use of tagged values,

■

For all the reasons on the previous slide, and

■

Because it enables information exchange between the system and the 4GL

→

Information exchange ...

■

System to 4GL:

•

System-level InputEvents (next section) store mouse information in TopForm tagged values

•

In the 4GL, use the InputEvent LastMouseAction method to access this information

■

4GL to system:

•

The new restyling behaviours are applied – whether at design time or runtime – as field-level tagged value definitions, using 4GL code

•

At runtime the system-level processing uses the taggedvalue-related methods to access these definitions in the frame fields, and execute the behaviours

23

Confidential © 2014 Actian Corporation

#### 4GL to System – executing predefined behaviors:

With the new sprites and InputEvent/Response processing, field and frame appearance can be much richer, and match chosen styles

- There is system support for the underlying generic mechanisms,
- but the actual behaviour of a given style has to be customized, and that means 4GL

So, we (and you) use 4GL to predefine the style behaviour as TaggedValues, and store them

- See Setup Frame capability

Now OpenROAD runtime can see the stored behaviors in the tagged values when the frame starts up, and do the work,

- Without any need for 4GL code or events

More about this in the next two sections

## ❑ Storable Defined (ready-to-use) Behaviors ④

➔ OpenROAD 6.2 introduces a major paradigm shift (see ①):

- 4GL Event granularity is **whole field**
  - Field shapes are rectangular
  - Field “movement” is whole field, and is limited by widget overhead
  - Event granularity is **icon** (sprite)
  - Field shapes are complex
  - Field “movement” includes sprite click, drag and hover, timed sequences, multiple independent elements
- The paradigm shift makes it cost-effective to provide all these needed flexibilities in OpenROAD ...
  - ...provided we can work at a finer response-granularity than the 4GL events offer

## ... Storable Defined (ready-to-use) Behaviors ...

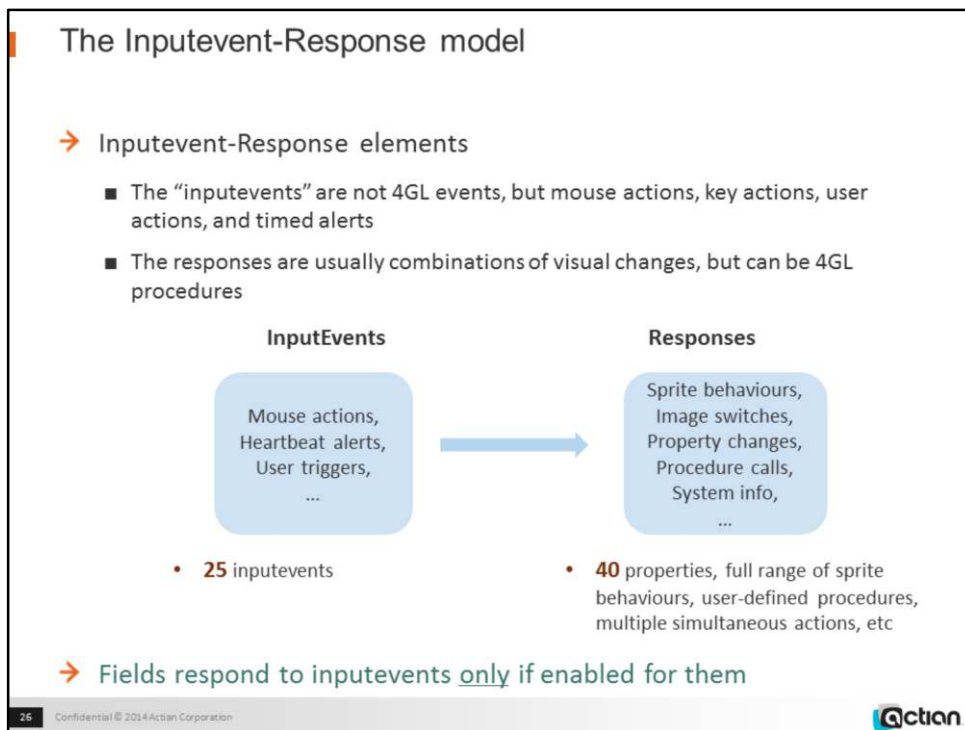

- ➔ The solution to the granularity requirement involves a further paradigm shift: inputevents and defined behaviors

- 4GL-display-event triggers
- Userevent alerts: CPU-intensive and queued
- Range of 4GL events is restricted, because:
  - Mousemove etc too costly
  - 4GL event model is at optimum
  - Backward compatibility needed
- Mouse-event triggers
- Heartbeat alerts: efficient and synchronous
- Response-granularity is unrestricted, so:
  - Sub-field needs can be met
  - Can respond to more user actions
  - Still backwardly compatible
- Can still invoke 4GL for logic when needed

■ Inputevent triggers are finer granularity than 4GL event triggers

■ No 4GL events or 4GL code are involved (except where you actually want them)

Two ways to enable a field for inputevents:

```

/*
** Create an “inputevent_enabled” taggedvalue in the field
** (for use if and only if the behaviour does not involve a BgBitmap)
*/
fld.SetTaggedValue(tag='inputevent_enabled');
/*
** Apply the InputEvent ActivateFields method to the field
** (ensures each listed field has a BgBitmap and a suitable BgDisplayPolicy)
*/
IE.ActivateFields(fields=fields, bitmap=bitmap);

```

<p><b>InputEvents:</b></p> <p>IE_KEYDOWN    IE_RMOUSEDLCL</p> <p>IE_KEYUP       K</p> <p>IE_SYSKEYDOWN</p> <p>IE_SYSKEYUP    IE_MMOUSEDOW</p> <p>IE_MOUSEMOVE N</p> <p>IE_LMOUSEDOWNIE_MMOUSEUP</p> <p>IE_LMOUSEUP</p> <p>IE_LMOUSEDLCLIE_MMOUSEDLCL</p> <p>IE_LMOUSEDLCL</p> <p>IE_NCMOUSEHOVER</p> <p>IE_MOUSEHOVER</p> <p>IE_SETFOCUS</p> <p>IE_LOSEFOCUS</p> <p>IE_MOUSEENTER</p>	<p>IE_INIT                    //Initialization (not initialize) event</p> <p>IE_MOVEPOINT            //The most recent move event at this</p> <p>                             timepoint</p> <p>IE_PULSE                  //Pulse-alert event (heartbeat alert, every 1</p> <p>                             second)</p> <p>IE_TICKPOINT            //Registered heartbeat-alert event</p> <p>IE_USER                   //User-defined action (IE_USER+1,</p> <p>                             IE_USER+2, etc,</p> <p>                             are also available</p>	
---	--	--

IE\_RMOUSEDOWN  
IE\_MOUSEUP

## How are behaviors defined, and how are they stored?

### ➔ Each behavior is defined using

- An EventKey string, combining:
  - The mouse, key, alert, or user action (as an IE\_ constant)
  - The modifier key(s), if any (as KB\_ constants)
  - The response code (as an RE\_ constant)
- A Response object, providing the essential element(s) of the particular response:
  - StringObject, for an imageindex or spritemap or nested behavior
  - Field, for a display behavior
  - ProcHandle, for a 4GL-coded behavior
  - Cursor bitmap, for cursor-change behaviors
  - TaggedValue, for timed/animation behaviors
  - Arrays, for sets of simultaneous behaviors
- The InputEvent Helper Class has methods that make all of this easy to specify

## ... How are behaviors defined, and how are they stored? ...

- ➔ All defined behaviors are stored in a field tagged value
  - Using the tag name “event\_responses”
  - The tagged value may belong to a display field (for behaviors specific to that field), or to the frame’s TopForm (for responses common to many fields)
    - For example, the Windows7 styling behaviors are defined at TopForm level
- ➔ Each behavior is stored as one of the tagged value’s KeyedItems
  - Using the Eventkey value as the lookup key
  - Example – the Windows7 default mouseover highlighting:
    - Two stored behaviors, one for the mouseentry, one for the mouseexit
    - Each applies a different imageindex to the background bitmap
      - so that a different background displays when the mouse is over the field
- ➔ Behaviors can be stored permanently or runtime-only
  - Permanently: in the frame’s framesource fields,
  - Runtime-only: in the frameexec fields, or with availability=TVA\_TEMPORARY

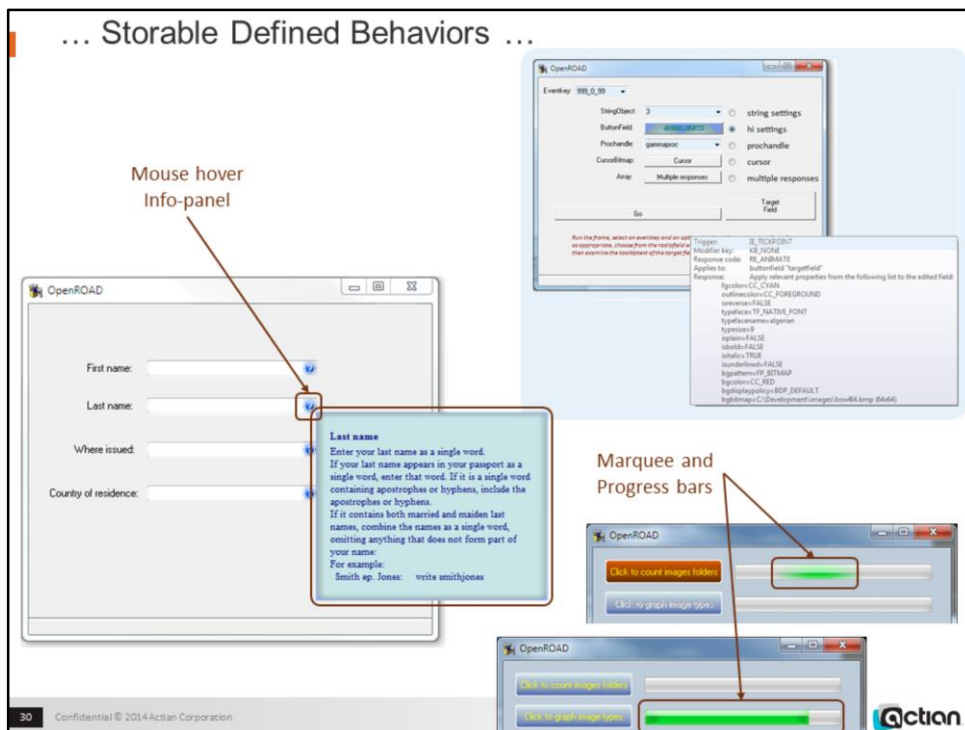

... How are behaviors defined, and how are they stored? –  
Example (Windows7 highlighting)

➔ To highlight on mouseenter, we need:

- Eventkey: IE\_MOUSEENTER, KB\_NONE, RE\_OTHERBUTTON
  - 995\_0\_89
- Response: StringObject set to the highlight imageindex
  - "2"
- Behaviour stored in the frame's topform

➔ We use InputEvent (Helper Class) methods to store the behavior:

```
eventkey = IE.EventKey(action=IE_MOUSEENTER, modifierkey=KB_NONE,  
                      responsecode=RE_OTHERBUTTON);  
response = IE.Response(type='image', imageindex=2);  
IE.LoadEventBehavior(location=frame.TopForm, eventkey=eventkey,  
                    responsetype='event_responses', response=response);
```

### Demo:

**D201504\_DefinedResponses\_Panel –cPassportDetails**

Run the frame

Hover the mouse over any of the “?” icons

An infopanel describing that field will appear

Note that no runtime code is involved in each popup response

### Demo:

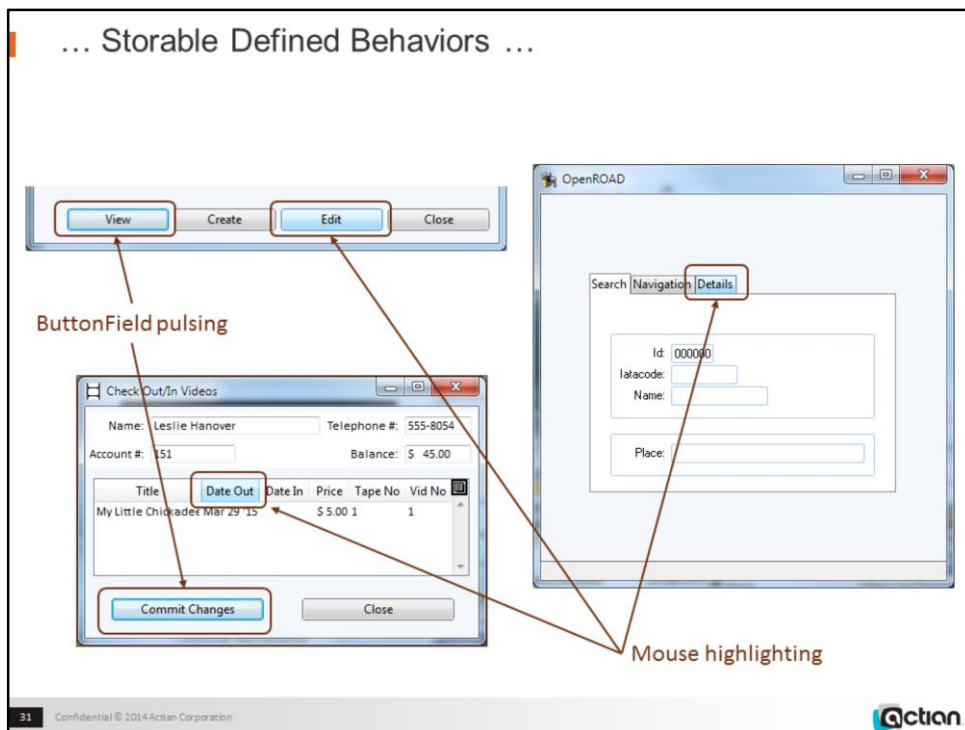

**D201504\_DefinedResponses –cDecodeDefinedBehavior**

Run the frame

Continue as instructed (instructions on frame)

Note that each resultant tooltip text identifies what combination of mouse or timer action and modifier key will produce what response, based on the selections that were made.

Note that you can have multiple simultaneous responses to a single action.

#### Demo:

D201504\_VideosConverted

Run application

Choose Check Out option

Enter 151 as customer account

Ctrl-Shift-Tab to move focus to "Commit Changes"

Hover mouse over Date Out column header

#### Demo:

D201504\_BitmapmedTabfolderTabs -cBDPTabHighlighting

Mouse vertically over an unselected tab

- The tab will highlight

#### Storable Defined Behaviors in Restyling (see Videos demo):

- Restyling is applied to ButtonFields, EntryFields, TableField headers, TabFolder tabs, SubForms, other compositefields, FreeTrims, Mainbars, RectangleShapes, ControlButtons.
- Most other fields are already W7 style, since we used native widgets for them.
- Field fonts are changed to Segoe UI 9

## ... Storable Defined Behaviors – summary of features

- ➔ Defined as tagged value items
- ➔ Created and stored using Helper Userclass methods
- ➔ Predefined using Setup Frames
- ➔ Executed (for responsive fields):
  - Automatically in response to WindowManager events
  - Automatically in response to Heartbeat-scheduled alerts
  - On demand in response to TriggerEventBehavior4GL calls
- ➔ Responding with single, multiple or time-based responses
  - Image-switch, sprite-display, display-properties changed, 4GL processing, combination and animation effects
  - Any degree of complexity
- ➔ Essential for OpenROAD 6.2 Windows7 restyling

## □ Helper Classes ⑤

- One more paradigm shift ...
- New Helper UserClasses, added to the Core application (so always available):
  - InputEvent - provides all the methods to define, schedule, trigger, manipulate or stop the range of defined behaviours
  - SpriteDescriptor – provides all the methods to handle field-background sprites
  - RequestManager – provides frame-management support for displays generated in an active\_displayframetemplate
- All processing using defined behaviors, sprites, and generated displays should make maximum use of these classes, as
  - They greatly simplify the handling of these features
  - They are used throughout the example code provided with OpenROAD 6.2
  - They are detailed in the documentation
  - They can be inherited and customized in helper classes you create

## InputEvent Class

→ Available via a Global Variable in Core, called IE

- No need to declare your own

→ Methods:

- EventKey - create an eventkey
- Response - package a response
- LoadEventBehavior - store a defined behaviour in a taggedvalue
- RemoveEventBehavior - remove a stored defined behaviour
- TriggerEventBehavior - trigger execution of a specified behavior
- QueueResponse - put response on the 4GL event queue for execution
  
- ActivateFields - make specified field(s) responsive to input actions
- LastInputAction - store details of a mouse action in the attributes, including which sprite(s) were touched

34

### QueueResponse Method:

Frames can only execute properly if called from 4GL code triggered (directly or indirectly) by an OpenROAD event that has been handled by the 4GL Event Queue. (This is why OpenROAD Server applications cannot handle frame calls).

InputEvent responses bypass the 4GL Event Queue, so if you need your ProcHandle (4GL procedure) response to call a frame, for example an info-popup, you need a way for it to queue its processing. The QueueResponse Method provides that.

## SpriteDescriptor Class

### → Attributes

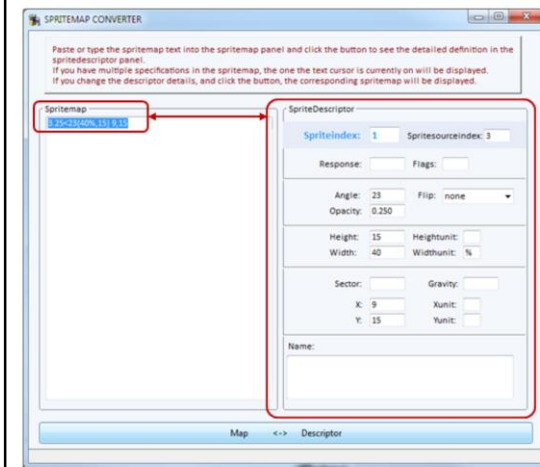

- These define a sprite or sector's position, size, identity, and (sprite-only) source-image, opacity, orientation, behaviour
  - Sprite built-in behaviours: drag, mouseover highlight, cursor-change

### → Methods:

- |                  |   |
|------------------|---|
| ■ ApplySectorMap | - apply a sectormap* to the field background      |
| ■ ApplySpriteMap | - apply a spritemap* to the field background      |
| ■ SpriteImage    | - return the source and actually-displayed images |
| ■ SpriteKey      | - eventkey for sprite-specific behaviors          |
| ■ SpriteMap      | - return the encoded spritemap as a StringObject  |
| ■ WhichSector    | - find by location or index and return a sector   |
| ■ WhichSprite    | - find by location or index and return a sprite   |

\* These two methods each accept an array of SpriteDescriptor, and internally convert it to a sectormap/spritemap which they apply to the field background

## SpriteDescriptor and SpriteMap

This demo utility accepts cut-and-pasted (or typed) encoded SpriteMap strings, and shows the sprite settings they contain.

SpriteDescriptors are too big and unwieldy to handle the instant graphical changes that sprite displays require,

- So behind the scenes they are encoded as a SpriteMap textstring

The SpriteDescriptor Methods mean that you do not need to work with SpriteMaps,

- But you will sometimes see them, in the debugger for example

### Demo:

D201504\_SpritemapConverter –cSpritemapConverter

Click the button

- the attribute fields on the right fill with values parsed from the example definition string on the left

Amend any of the SpriteDescriptor attribute field values

Click the button

- the spritemap on the left changes to reflect the new spritedescriptor settings

RequestManager Class

- Provides generic functions to run standard frame processes in generated frames
  - Business-Item browsing, creation and change; drill-into navigation; item copy-cut-paste-hide; frame initialize and close; tablefield row sort; and more
  - Each of these can be overdefined or extended by you
  - Intended for use with active\_display template (or your custom version of it)

→ Attributes

- Item - the principal object the frame is displaying
- Items - the set of ready-to-display objects for step-through
- ChoiceList - a choicelist of Items to display, derived from “filter”

→ Methods:

- RespondToRequest - find and execute the specified function
- AncestorByProperty - find the first parentfield with the specified property
- AllAttributes - return all a UserClass’s attribute definitions (AttributeObjects), including the inherited ones

## RequestManager, Active\_Display, and RespondToRequest

RequestManager is for use with frames created from the active\_display FrameTemplate although you can take advantage of its features for other purposes

Active\_display frames treat each enduser action as a request for a particular response

For example: Clicking the Save Button is a request for a Business-Item-Save response

Each active\_display frame contains just 60 lines of code (which you can add to or delete) the RequestManager does all the 4GL work, via the **RespondToRequest** method.

RequestManager holds all the generic functions for these frames

Each of these can be overdefined in the frame by a local procedure.

## Overdefining and extending the functions:

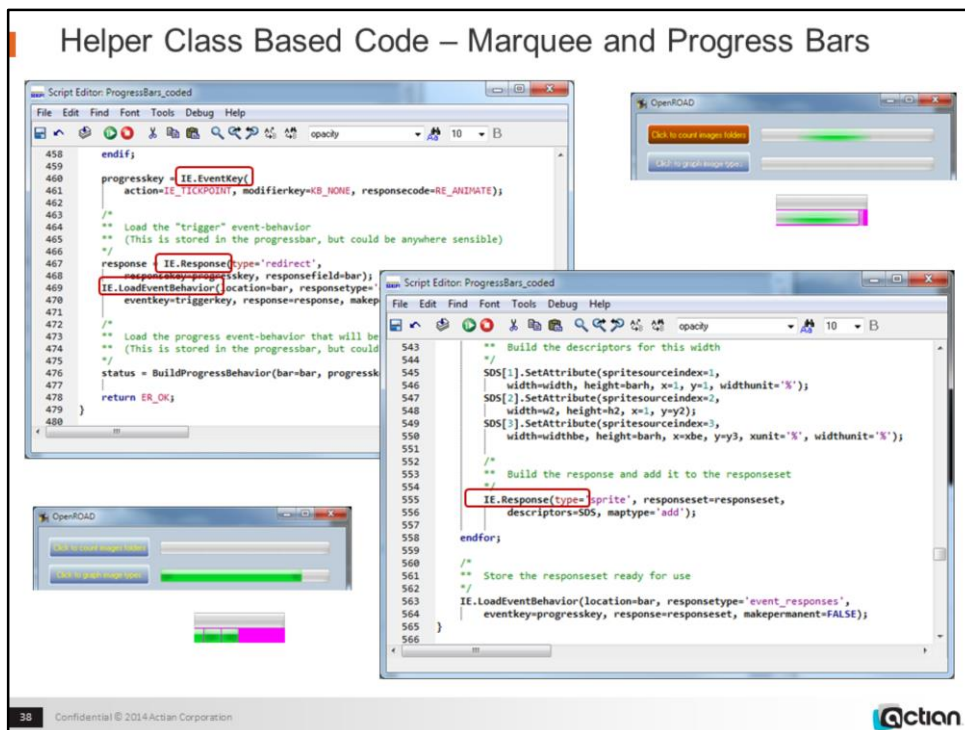

In RequestManager, each function is a “case” within one of the following local procedures:

FrameRequest, DataRequest, TblRequest, OtherRequest.

Each procedure has the same interface (action=varchar, trigger=fieldobject, info=object).

To override the Close function (which belongs to FrameRequest), for example:

- Create a FrameRequest local procedure in your frame, with the standard interface.
- In it put a **case action** statement, with a case of ‘close’:
- In the close case, put or call the processing you want executed instead of the RequestManager default.

w4gldev runimage workbnch.img -Tall -/appflags profile=or62demos  
 application=d201504\_definedresponses\_sprites component=progressbars\_coded  
 command=openscript#520

Note the way the EventKey and Response and LoadEventBehavior methods  
 combine to create and store a defined behavior

Go to line 603

Note that the code samples here are both **setup** code extracts, not needed at  
 runtime

They use the InputEvent and SpriteDescriptor Helper Class methods.  
 Note that the "Compound bitmaps, sprites, animations, defined behaviors" slide  
 shown earlier has an extract of **runtime** code,  
 also using the InputEvent and SpriteDescriptor Helper Class methods.

## ❑ Setup Frames ⑤

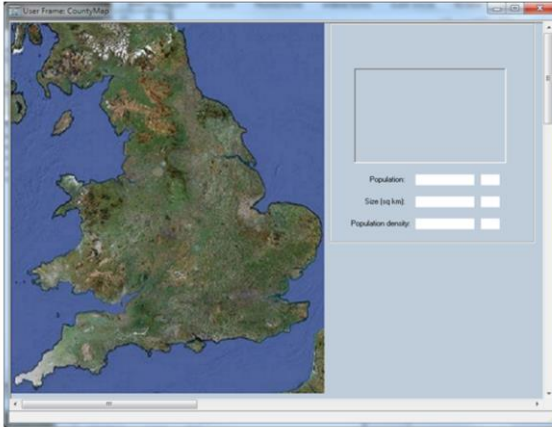

- ➔ Existing applications have a lot of “setup” code in each frame
  - Code that should have been run beforehand, if the results could be saved
  - Not just in the initialize block either!
- ➔ The Property Inspector now has as SetupName option
  - Specify the setup frame’s name, and it is called from the frame editor, and passed the target frame’s framesource (as the “frame” parameter)
  - In the setup frame put all the setup changes that need to be preapplied to the framesource, for example:
    - Field property changes unavailable in, or too laborious to apply from, the StyleSheet or PropertyInspector (bias settings, tabfolder settings, tablefield settings, ...)
    - Computation of ready-to-use data from fixed-data sources (lists, trees, decodes ...)
    - Changes to the target frame’s code (maybe ...)
    - (In 6.2) Storage of defined behaviors, InputEvent-activation of fields, ...
  - When the setup has run, and the target frame is saved, the setup is in place – and the target frame’s old setup code is no longer needed

## ... Setup Frames ...

### County Demographics setup frame example

#### → Initial state

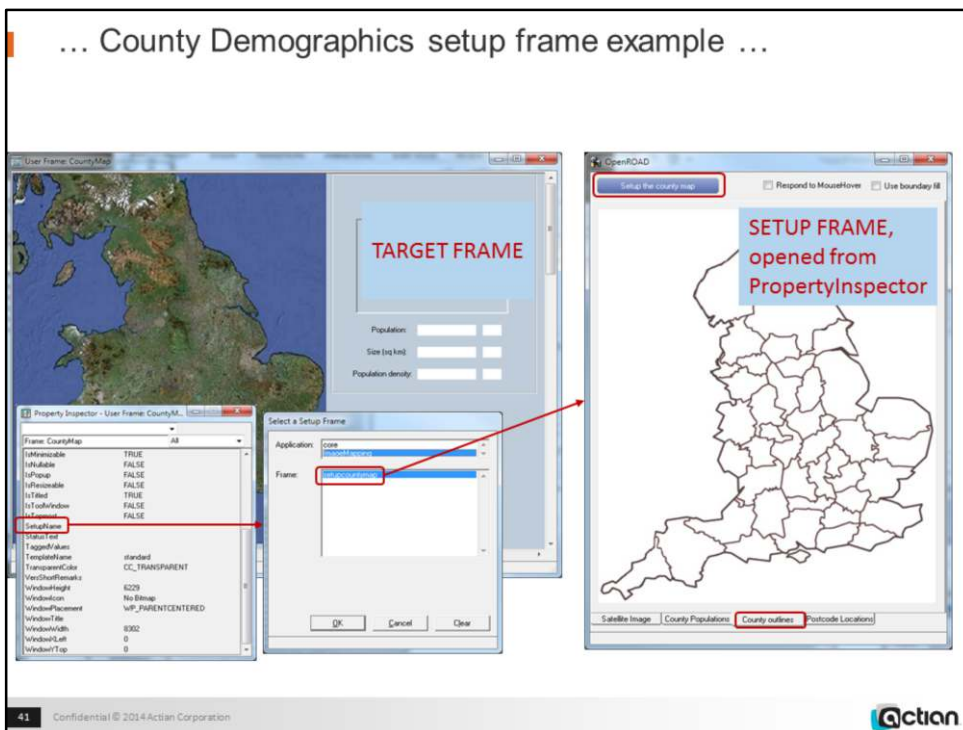

#### ■ frame contains:

- Placeholder (JPG) satellite image
- Runtime code and fields

#### ■ frame also requires:

- County demographic data
- County boundary coordinates
- Mask image, each county uniquely coloured
- Map-ready (BMP) satellite image

## ... County Demographics setup frame example ...

### Demo:

`w4gldev runimage workbench.img -Tall -/appflags profile=or62demos application=D201504_ImageMapping component=countymap command=open`

The CountyMap frame is opened for edit

Select the SetupName entry in the Property Inspector

The Setup Frame dialog will appear

Select the "D201504\_ImageMapping" application and the "setupcountymap" frame,  
and click OK

The SetupCountyMap setup frame will run

Click the "County Outlines" tab

An outline map of English counties will appear

Click the "Setup the county map" button

After a few seconds each county will be coloured a different shade of grey

Note that the CountyMap frame, the one that the enduser will see at runtime, has been setup and ready to go:

- the grey (mask) image, the county boundary coordinates, and the cross-reference of these to the county demographic data, have all been generated by the setup frame, and applied to the CountyMap frame

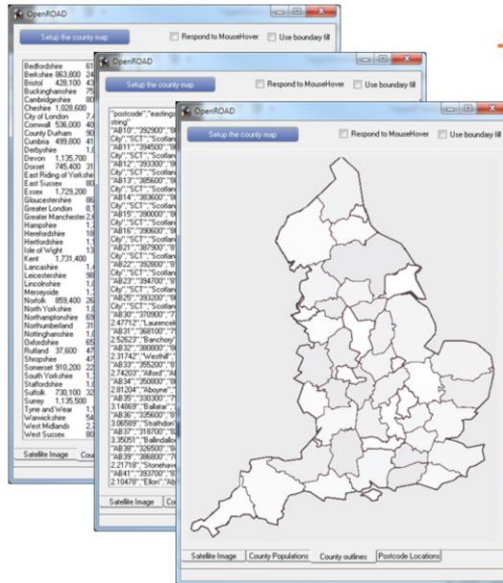

Close the setup frame

Run the county map frame

Click any point in SouthEast England on the satellite image to confirm that setup has worked correctly

- the county under the mouse is outlined in green, the name and demographic data for that county appear on the right, and a satellite image of that county appears above the data

## Running the Mapping setup-frame

➔ What does this frame do?

- Parses UK postcode location data
  - Data is publicly available
- Picks a postcode for each county
- Maps each county boundary and uniquely colours each county, creating a "mask"
  - Using FillBitmap
- Parses the county population data and crosslinks it by colour
- Stores the ready-to-use mapped data in the target frame
  - When the target frame is saved, the mapped data will be saved
- Job done.

Around 300 executing statements in the setup frame 4GL, leaving just 70 in the runtime frame.

## ... County Demographics setup frame example ...

### → Ready-to-use state

#### ■ frame now contains:

- County demographic data
- County boundary coordinates
- Mask image, each county uniquely coloured
- Map-ready (BMP) satellite image
- Runtime code and fields

43 Confidential © 2014 Action Corporation

### Demo (continued):

Run the CountyMap frame

Click somewhere in SE England.

(Note – the source data was missing some counties; clicking on those gives incorrect results)

How does it work? Simply and generically:

- The colour of the mask at the mouse location identifies the county
- That county's name and data is displayed
- That county's border coordinates are used to draw the outline
- A rectangle including the county is extracted as an image
- FillBitmap fills everywhere outside of the border with the border colour
- The image is displayed treating the border color as transparent.

✓ Providing generic enabling facilities to underpin the business-need features, both current and future

1. Bitmapped backgrounds with built-in bordering and double-buffering
2. Compound bitmaps, sprites and animations
3. Tagged Values/Items
4. Storable defined-behaviours
5. Helper classes and Setup frames
6. Many enabling property and method changes to field and data classes
  - TreeViews, TableFields, TabFolders; String & BitmapObjects; and much more
7. Enhanced PropertyChanged facilities
8. Database and display heuristics
9. Downloadable IngresNet
10. LoadnRun deployment

Items 6 to 8 are covered in the fourth presentation

Items 9 and 10 were covered in the second presentation

## What was covered

### ➔ OpenROAD 6.2 – New generic features in more detail, Part I

- The third of four presentations covering OpenROAD 6.2
  - ➔ This presentation was the first of two reviewing in detail the new features in this release
- Features illustrated in the presentation require the first OpenROAD 6.2 patch
  - p14746 or later

# Thank you
